The purpose of this assignment is to write a program to implement autocomplete for a given set of N strings and nonnegative weights. That is, given a prefix, find all strings in the set that start with the prefix, in descending order of weight.

Autocomplete is an important feature of many modern applications. As the user types, the program predicts the complete query (typically a word or phrase) that the user intends to type. Autocomplete is most effective when there are a limited number of likely queries. For example, the Internet Movie Database uses it to display the names of movies as the user types; search engines use it to display suggestions as the user enters web search queries; cell phones use it to speed up text input.

In these examples, the application predicts how likely it is that the user is typing each query and presents to the user a list of the top-matching queries, in descending order of weight. These weights are determined by historical data, such as box office revenue for movies, frequencies of search queries from other Google users, or the typing history of a cell phone user. For the purposes of this assignment, you will have access to a set of all possible queries and associated weights (and these queries and weights will not change).

The performance of autocomplete functionality is critical in many systems. For example, consider a search engine which runs an autocomplete application on a server farm. According to one study, the application has only about 50ms to return a list of suggestions for it to be useful to the user. Moreover, in principle, it must perform this computation for every keystroke typed into the search bar and for every user!

In this assignment, you will implement autocomplete by sorting the queries in lexicographic order; using binary search to find the set of queries that start with a given prefix; and sorting the matching queries in descending order by weight.

Problem 1. (Autocomplete Term) Implement an immutable comparable data type Term in Term.java that represents an autocomplete term: a string query and an associated real-valued weight. You must implement the following API, which supports comparing terms by three different orders: lexicographic order by query string (the natural order); in descending order by weight (an alternate order); and lexicographic order by query string but using only the first r characters (a family of alternate orderings). The last order may seem a bit odd, but you will use it in Problem 3 to find all terms that start with a given prefix (of length r).

Term(String query) initialize a term with the given query string and zero weight
Term(String query, long weight) initialize a term with the given query string and weight
static Comparator<Term> byReverseWeightOrder() compare the terms in descending order by weight
compare the terms in lexicographic order but using only the
first r characters of each query
compare the terms in lexicographic order by query
string toString() a string representation of the term

Corner cases. The constructor should throw a java.lang.NullPointerException if query is null and a java.lang.IllegalArgumentException if weight is negative. The byPrefixOrder() method should throw a java.lang.IllegalArgumentException if r is negative.

Performance requirements. The string comparison functions should take time proportional to the number of characters needed to resolve the comparison.

```
$ java Term data/cities.txt 5
Top 5 by lexicographic order:
2200
        's Gravenmoer, Netherlands
19190
        's-Gravenzande, Netherlands
134520
       's-Hertogenbosch, Netherlands
3628
        't Hofke, Netherlands
246056 A Corua, Spain
Top 5 by reverse-weight order:
14608512
                Shanghai, China
13076300
                Buenos Aires, Argentina
12691836
                Mumbai, India
                Mexico City, Distrito Federal, Mexico
12294193
11624219
                Karachi, Pakistan
```

Problem 2. (Binary Search Deluxe) When binary searching a sorted array that contains more than one key equal to the search key, the client may want to know the index of either the first or the last such key. Accordingly, implement a library of static methods BinarySearchDeluxe.java with the following API:

method	description
	the index of the first key
<pre>static <key> int firstIndexOf(Key[] a, Key key, Comparator<key> comparator)</key></key></pre>	in $a[]$ that equals the search key,
	or -1 if no such key
<pre>static <key> int lastIndexOf(Key[] a, Key key, Comparator<key> comparator)</key></key></pre>	the index of the last key
	in $a[]$ that equals the search key,
	or -1 if no such key

Corner cases. Each static method should throw a java.lang.NullPointerException if any of its arguments is null. You should assume that the argument array is in sorted order (with respect to the supplied comparator).

Performance requirements. The firstIndexOf() and lastIndexOf() methods should make at most $1 + \lceil \log N \rceil$ compares in the worst case, where N is the length of the array. In this context, a compare is one call to comparator.compare().

```
$ java BinarySearchDeluxe data/wiktionary.txt cook3
```

Problem 3. (Autocomplete) In this part, you will implement a data type that provides autocomplete functionality for a given set of string and weights, using Term and BinarySearchDeluxe. To do so, sort the terms in lexicographic order; use binary search to find the set of terms that start with a given prefix; and sort the matching terms in descending order by weight. Organize your program by creating an immutable data type Autocomplete in Autocomplete.java with the following API:

method	description
Autocomplete(Term[] terms)	initialize the data structure from the given array of terms
<pre>Term[] allMatches(String prefix)</pre>	all terms that start with the given prefix, in descending order of weight
<pre>int numberOfMatches(String prefix)</pre>	the number of terms that start with the given prefix

Corner cases. The constructor and each method should throw a java.lang.NullPointerException if its argument is null.

Performance requirements. The constructor should make proportional to $N \log N$ compares (or better) in the worst case, where N is the number of terms. The allMatches() method should make proportional to $\log N + M \log M$ compares (or better) in the worst case, where M is the number of matching terms. The numberOfMatches() method should make proportional to $\log N$ compares (or better) in the worst case. In this context, a compare is one call to any of the compare() or compareTo() methods defined in Term.

Data Under the data directory, we provide sample input files for testing. Each file consists of an integer N followed by N pairs of query strings and nonnegative weights. There is one pair per line, with the weight and string separated by a tab. A weight can be any integer between 0 and $2^{63}-1$. A query string can be an arbitrary sequence of Unicode characters, including spaces (but not newlines). For example, wiktionary.txt contains the 10,000 most common words in Project Gutenberg, with weights proportional to their frequencies.

```
$ more wiktionary.txt
10000
   5627187200
   3395006400
                 of
   2994418400
                 and
   2595609600
                 to
   1742063600
                 in
   1176479700
                 i
   1107331800
                 that
   1007824500
                 was
    879975500
                 his
       392323
                 calves
```

Visualization Client The program AutocompleteGUI takes the name of a file and an integer k as command-line arguments and provides a GUI for the user to enter queries. It presents the top k matching terms in real time. When the user selects a term, the GUI opens up the results from a Google search for that term in a browser.

\$ java AutocompleteGUI data/cities.txt 7

Files to Submit

1. Term.java

- 2. BinarySearchDeluxe.java
- 3. Autocomplete.java
- 4. report.txt

Before you submit:

• Make sure your programs meet the input and output specifications by running the following command on the terminal:

```
$ python run_tests.py -v [<problems>]
```

where the optional argument cproblems lists the problems (Problem1, Problem2, etc.) you want to test; all the problems are tested if no argument is given.

• Make sure your programs meet the style requirements by running the following command on the terminal:

```
$ check_style cprogram >
```

where cprogram> is the .java file whose style you want to check.

• Make sure your report isn't too verbose, doesn't contain lines that exceed 80 characters, and doesn't contain spelling/grammatical mistakes

Acknowledgements This project is an adaptation of the Autocomplete Me assignment developed at Princeton University by Matthew Drabick and Kevin Wayne.
